

Lcd inverter voltage

Overview

Typically, over 1000 volts RMS is required to initiate lamp operation, with sustaining voltages ranging from 200VAC to 800VAC. To date, the high voltage section of backlight “inverters” has been designed around magnetic transformers.

Typically, over 1000 volts RMS is required to initiate lamp operation, with sustaining voltages ranging from 200VAC to 800VAC. To date, the high voltage section of backlight “inverters” has been designed around magnetic transformers.

The liquid crystal display (LCD) has become ubiquitous. It is in use everywhere, from personal computers of all sizes to point-of-sale terminals as well as instruments, autos and medical apparatus. The LCD utilizes a cold cathode fluorescent lamp (CCFL) as a light source to back light the display.

This application note describes how to use the Agilent N6700 Modular Power System (MPS) to test the backlight inverter of a Liquid Crystal Display (LCD). Testing the inverters used to power and control the backlights of LCDs (cold-cathode-fluorescent-lamp, or CCFL) requires multiple sequenced.

Many LCD display modules require a negative or positive voltage that is higher than the logic voltage used to power an LCD. This voltage, called V_L , Vee or the bias voltage, would require a second power supply in the application device. If this power source is not available the LCD bias voltage.

The LCD inverter is an essential part of many laptops, monitors, and LCD screens. It helps power the screen’s backlight by converting the direct current (DC) from the laptop into the alternating current (AC) needed by the backlight. Without the inverter, the screen would remain dark. The inverter is.

The main function of the LCD inverter board is to convert the direct current (DC) power from the power supply unit into an alternating current (AC) that is needed to power the backlight. This AC current is then used to generate the necessary voltage required by the cold cathode fluorescent lamps.

Most Liquid Crystal Display modules require a Positive or Negative voltage that is

higher than the logic voltage used to power the LCD. This voltage, called VI, VEE or Bias voltage, requires a second power supply. If this power source is not available, the LCD Bias voltage must be generated from an.
